jwguo@hytc.edu.cn

Abstract. Recently, Z.-W. Sun introduced two kinds of polynomials related to the Delannoy numbers, and proved some supercongruences on sums involving those polynomials. We deduce new summation formulas for squares of those polynomials and use them to prove that certain rational sums involving even powers of those polynomials are integers whenever they are evaluated at integers. This confirms two conjectures of Z.-W. Sun. We also conjecture that many of these results have neat q -analogues.

Keywords: Delannoy number; q -Delannoy numbers; q -binomial coefficients; Zeilberger algorithm

1 Introduction

It is well known that, for any $m, n \geq 0$, the number

$$\sum_{k=0}^n \binom{n}{k} \binom{m}{k} 2^k = \sum_{k=0}^n \binom{n}{k} \binom{n+m-k}{n},$$

called a *Delannoy number*, counts lattice paths from $(0, 0)$ to (m, n) in which only east $(1, 0)$, north $(0, 1)$, and northeast $(1, 1)$ steps are allowed. Recently, Z.-W. Sun [15] introduced the following polynomials

$$d_n(x) = \sum_{k=0}^n \binom{n}{k} \binom{x}{k} 2^k,$$

$$s_n(x) = \sum_{k=0}^n \binom{n}{k} \binom{x}{k} \binom{x+k}{k},$$

and established some interesting supercongruences involving $d_n(x)$ or $s_n(x)$, such as

$$\sum_{k=0}^{p-1} (2k+1)d_k(x)^2 \equiv \begin{cases} -x \pmod{p^2}, & \text{if } x \equiv 0 \pmod{p}, \\ x+1 \pmod{p^2}, & \text{if } x \equiv -1 \pmod{p}, \\ 0 \pmod{p^2}, & \text{otherwise,} \end{cases} \quad (1.1)$$

$$\sum_{k=0}^{p-1} (2k+1)s_k(x)^2 \equiv 0 \pmod{p^2}, \quad (1.2)$$

where p is an odd prime and x is a p -adic integer.

Recall that a polynomial $P(x)$ in x with real coefficients is called *integer-valued*, if $P(x) \in \mathbb{Z}$ for all $x \in \mathbb{Z}$. In this paper, we shall prove the following generalizations of (1.1) and (1.2), which were originally conjectured by Z.-W. Sun (see [15, Conjectures 6.1 and 6.12]).

Theorem 1.1 *Let m and n be positive integers. Then all of*

$$\begin{aligned} \frac{x(x+1)}{2n^2} \sum_{k=0}^{n-1} (2k+1)d_k(x)^2, \quad \frac{1}{n} \sum_{k=0}^{n-1} (2k+1)d_k(x)^{2m}, \quad \frac{1}{n} \sum_{k=0}^{n-1} (-1)^k (2k+1)d_k(x)^{2m}, \\ \frac{1}{2n^2} \sum_{k=0}^{n-1} (2k+1)s_k(x)^2, \quad \frac{1}{n} \sum_{k=0}^{n-1} (2k+1)s_k(x)^{2m}, \quad \frac{1}{n} \sum_{k=0}^{n-1} (-1)^k (2k+1)s_k(x)^{2m} \end{aligned}$$

are integer-valued.

We shall also prove the following result, which will play an important role in our proof of Theorem 1.1.

Theorem 1.2 *Let m and n be positive integers and let j, k be non-negative integers. Then*

$$\frac{(n-k)(k+1)}{n} \binom{n+k}{2k} \binom{m+1}{k+1} \binom{m+k}{k+1}$$

and

$$\frac{1}{k+1} \binom{n-1}{k} \binom{n+k}{k} \binom{2k}{j+k} \binom{m+k}{2k} \binom{m}{j} \binom{m+j}{j}$$

are integers.

The paper is organized as follows. In the next section, we shall give a q -analogue of Theorem 1.2. In Section 3, we mainly give a single-sum expression for $d_n(x)^2$, a new expression for $s_n(x)^2$, and recall a recent divisibility result of Chen and Guo [3] concerning multi-variable Schmidt polynomials. The proof of Theorem 1.1 will be given in Section 4. We propose some related open problems in the last section.

2 A q -analogue of Theorem 1.2

Recall that the q -binomial coefficients are defined by

$$\begin{bmatrix} n \\ k \end{bmatrix} = \begin{cases} \prod_{i=1}^k \frac{1 - q^{n-k+i}}{1 - q^i}, & \text{if } 0 \leq k \leq n, \\ 0, & \text{otherwise.} \end{cases}$$

The following is our announced strengthening of Theorem 1.2.

Theorem 2.1 *Let m and n be positive integers and let j, k be non-negative integers. Then*

$$\frac{(1 - q^{n-k})(1 - q^{k+1})}{(1 - q)(1 - q^n)} \begin{bmatrix} n+k \\ 2k \end{bmatrix} \begin{bmatrix} m+1 \\ k+1 \end{bmatrix} \begin{bmatrix} m+k \\ k+1 \end{bmatrix} \quad (2.1)$$

and

$$\frac{1 - q}{1 - q^{k+1}} \begin{bmatrix} n-1 \\ k \end{bmatrix} \begin{bmatrix} n+k \\ k \end{bmatrix} \begin{bmatrix} 2k \\ j+k \end{bmatrix} \begin{bmatrix} m+k \\ 2k \end{bmatrix} \begin{bmatrix} m \\ j \end{bmatrix} \begin{bmatrix} m+j \\ j \end{bmatrix} \quad (2.2)$$

are polynomials in q with non-negative integer coefficients.

Proof of Theorem 2.1. It suffices to show that (2.1) and (2.2) are polynomials in q with integer coefficients, since the proof of the non-negativity is exactly the same as those in [7,8]. We shall accomplish this by decomposing q -binomial coefficients into cyclotomic polynomials.

It is well known that

$$q^n - 1 = \prod_{d|n} \Phi_d(q),$$

where $\Phi_d(q)$ denotes the d -th cyclotomic polynomial in q . For any real number x , let $\lfloor x \rfloor$ denote the largest integer less than or equal to x . Then

$$\frac{(1 - q^{n-k})(1 - q^{k+1})}{(1 - q)(1 - q^n)} \begin{bmatrix} n+k \\ 2k \end{bmatrix} \begin{bmatrix} m+1 \\ k+1 \end{bmatrix} \begin{bmatrix} m+k \\ k+1 \end{bmatrix} = \prod_{d=2}^{\max\{m+k, n+k\}} \Phi_d(q)^{e_d},$$

with

$$\begin{aligned} e_d = & \chi(d \mid n-k) + \chi(d \mid k+1) - \chi(d \mid n) + \left\lfloor \frac{n+k}{d} \right\rfloor + \left\lfloor \frac{m+1}{d} \right\rfloor + \left\lfloor \frac{m+k}{d} \right\rfloor \\ & - \left\lfloor \frac{n-k}{d} \right\rfloor - \left\lfloor \frac{2k}{d} \right\rfloor - \left\lfloor \frac{m-k}{d} \right\rfloor - \left\lfloor \frac{m-1}{d} \right\rfloor - 2 \left\lfloor \frac{k+1}{d} \right\rfloor, \end{aligned}$$

where $\chi(\mathcal{S}) = 1$ if \mathcal{S} is true and $\chi(\mathcal{S}) = 0$ otherwise. The number e_d is obviously non-negative, unless $d \mid n$, $d \nmid n-k$ and $d \nmid k+1$.

So, let us assume that $d \mid n$, $d \nmid n - k$ and $d \nmid k + 1$. Since one of k and $k + 1$ is even, we must have $d \geq 3$. Let $\{x\} = x - \lfloor x \rfloor$ denote the fraction part of x . We consider three cases: If $0 < \{\frac{k}{d}\} < \frac{1}{2}$, then

$$\left\lfloor \frac{n+k}{d} \right\rfloor - \left\lfloor \frac{n-k}{d} \right\rfloor - \left\lfloor \frac{2k}{d} \right\rfloor = \left\lfloor \frac{d+k}{d} \right\rfloor - \left\lfloor \frac{d-k}{d} \right\rfloor - \left\lfloor \frac{2k}{d} \right\rfloor = 1.$$

Namely, e_d is non-negative. If $\{\frac{k}{d}\} \geq \frac{1}{2}$ and $\{\frac{m}{d}\} \geq \{\frac{k}{d}\}$, then noticing that $d \nmid k + 1$, we have $\{\frac{m-1}{d}\} \geq \frac{1}{2} - \frac{1}{3} > 0$, and so

$$\left\lfloor \frac{m+k}{d} \right\rfloor - \left\lfloor \frac{m-1}{d} \right\rfloor - \left\lfloor \frac{k+1}{d} \right\rfloor = 1.$$

That is, e_d is also non-negative. If $\{\frac{k}{d}\} \geq \frac{1}{2}$ and $\{\frac{m}{d}\} < \{\frac{k}{d}\}$, then $\{\frac{k+1}{d}\} > \{\frac{k}{d}\} \geq \frac{1}{2}$, and so $\{\frac{m+1}{d}\} < \{\frac{k+1}{d}\}$, i.e.,

$$\left\lfloor \frac{m+1}{d} \right\rfloor - \left\lfloor \frac{m-k}{d} \right\rfloor - \left\lfloor \frac{k+1}{d} \right\rfloor = 1.$$

which means that e_d is still non-negative. This completes the proof of polynomiality of (2.1).

Similarly, we have

$$\frac{1-q}{1-q^{k+1}} \begin{bmatrix} n-1 \\ k \end{bmatrix} \begin{bmatrix} n+k \\ k \end{bmatrix} \begin{bmatrix} 2k \\ j+k \end{bmatrix} \begin{bmatrix} m+k \\ 2k \end{bmatrix} \begin{bmatrix} m \\ j \end{bmatrix} \begin{bmatrix} m+j \\ j \end{bmatrix} = \prod_{d=2}^{\max\{n+k, m+k, m+j\}} \Phi_d(q)^{e_d},$$

with

$$\begin{aligned} e_d = & -\chi(d \mid k+1) + \left\lfloor \frac{n-1}{d} \right\rfloor + \left\lfloor \frac{n+k}{d} \right\rfloor + \left\lfloor \frac{m+k}{d} \right\rfloor + \left\lfloor \frac{m+j}{d} \right\rfloor - \left\lfloor \frac{n}{d} \right\rfloor \\ & - \left\lfloor \frac{n-k-1}{d} \right\rfloor - \left\lfloor \frac{j+k}{d} \right\rfloor - \left\lfloor \frac{k-j}{d} \right\rfloor - \left\lfloor \frac{m-k}{d} \right\rfloor - 2 \left\lfloor \frac{k}{d} \right\rfloor - \left\lfloor \frac{m-j}{d} \right\rfloor - 2 \left\lfloor \frac{j}{d} \right\rfloor. \end{aligned}$$

The number e_d is obviously non-negative, unless $d \mid k + 1$.

Let $d \geq 2$ be a positive integer and $d \mid k + 1$. It is clear that $\{\frac{k}{d}\} = \frac{d-1}{d} \geq \frac{1}{2}$.

- If $d \nmid n$, then $\lfloor \frac{n-1}{d} \rfloor - \lfloor \frac{n}{d} \rfloor = 0$, and

$$\left\lfloor \frac{m+k}{d} \right\rfloor - \left\lfloor \frac{m-k}{d} \right\rfloor - 2 \left\lfloor \frac{k}{d} \right\rfloor \geq \left\lfloor \frac{2k}{d} \right\rfloor - 2 \left\lfloor \frac{k}{d} \right\rfloor = 1. \quad (2.3)$$

- If $d \mid n$, then $\lfloor \frac{n-1}{d} \rfloor - \lfloor \frac{n}{d} \rfloor = -1$ and the inequality (2.3) still holds. We consider three subcases:

- (i) For $\{\frac{m-k}{d}\} \geq \frac{2}{d}$, there holds

$$\left\lfloor \frac{m+k}{d} \right\rfloor - \left\lfloor \frac{m-k}{d} \right\rfloor - 2 \left\lfloor \frac{k}{d} \right\rfloor = 2.$$

(ii) For $\{\frac{m-k}{d}\} = \frac{1}{d}$, we have $d \mid m$. If $d \nmid j$, then

$$\left\lfloor \frac{m+j}{d} \right\rfloor - \left\lfloor \frac{m-j}{d} \right\rfloor - 2 \left\lfloor \frac{j}{d} \right\rfloor \geq \left\lfloor \frac{m}{d} \right\rfloor - \left\lfloor \frac{m-j}{d} \right\rfloor - \left\lfloor \frac{j}{d} \right\rfloor = 1,$$

while if $d \mid j$, then

$$\left\lfloor \frac{n+k}{d} \right\rfloor - \left\lfloor \frac{n-k}{d} \right\rfloor - \left\lfloor \frac{j+k}{d} \right\rfloor - \left\lfloor \frac{k-j}{d} \right\rfloor = \left\lfloor \frac{2k}{d} \right\rfloor - 2 \left\lfloor \frac{k}{d} \right\rfloor = 1. \quad (2.4)$$

(ii) For $\{\frac{m-k}{d}\} = 0$, we have $d \mid m+1$. If $d \nmid j$, then

$$\left\lfloor \frac{m+j}{d} \right\rfloor - \left\lfloor \frac{m-j}{d} \right\rfloor - 2 \left\lfloor \frac{j}{d} \right\rfloor \geq \left\lfloor \frac{m+j}{d} \right\rfloor - \left\lfloor \frac{m}{d} \right\rfloor - \left\lfloor \frac{j}{d} \right\rfloor = 1,$$

while if $d \mid j$, then the inequality (2.4) holds again.

Above all, we have proved that $e_d \geq 0$ in any case. This completes the proof of polynomiality of (2.2). \square

Remark. It was pointed out by the referee that a slightly shorter proof of $e_d \geq 0$ can be given by noticing that we may assume that $0 \leq n, k, m < d$.

It is easily seen that Theorem 1.2 follows from Theorem 2.1 by letting $q \rightarrow 1$.

3 Some auxiliary results

Z.-W. Sun [15, (1.7)] noticed that $d_n(-x-1) = (-1)^n d_n(x)$, which is also demonstrated by a formula in [14, p. 31]. This encourages us to find the following identity for $d_n(x)^2$.

Lemma 3.1 *Let n be a non-negative integer. Then*

$$d_n(x)^2 = \sum_{k=0}^n \binom{n+k}{2k} \binom{x}{k} \binom{x+k}{k} 4^k. \quad (3.1)$$

Proof. Denote the right-hand side of (3.1) by $S_n(x)$. Applying the Zeilberger algorithm (see [12, 13]), we have

$$(n+2)d_{n+2}(x) = (2x+1)d_{n+1}(x) + (n+1)d_n(x), \quad (3.2)$$

$$(n+1)^2 S_n(x) - (n^2 + 4n + 4x^2 + 4x + 5)(S_{n+1}(x) + S_{n+2}(x)) + (n+3)^2 S_{n+3}(x) = 0.$$

It follows from (3.2) that

$$(n+2)^2 d_{n+2}(x)^2 = (2x+1)^2 d_{n+1}(x)^2 + (n+1)^2 d_n(x)^2 + 2(n+1)(2x+1)d_{n+1}(x)d_n(x), \quad (3.3)$$

$$(n+2)d_{n+2}(x)d_{n+1}(x) = (2x+1)d_{n+1}(x)^2 + (n+1)d_{n+1}(x)d_n(x). \quad (3.4)$$

Substituting (3.3) twice into (3.4), and making some simplification, we immediately get

$$(n+1)^2 d_n(x)^2 - (n^2 + 4n + 4x^2 + 4x + 5) (d_{n+1}(x)^2 + d_{n+2}(x)^2) + (n+3)^2 d_{n+3}(x)^2 = 0.$$

Namely, the polynomials $d_n(x)^2$ and $S_n(x)$ satisfy the same recurrence. It is easy to see that $d_n(x)^2 = S_n(x)$ holds for $n = 0, 1, 2$. This completes the proof of (3.1). \square

Remark. The hypergeometric form of (3.1) is as follows:

$${}_2F_1 \left[\begin{matrix} -n, -x \\ 1 \end{matrix} ; 2 \right]^2 = {}_4F_3 \left[\begin{matrix} -n, -x, n+1, x+1 \\ 1, 1, \frac{1}{2} \end{matrix} ; 1 \right]. \quad (3.5)$$

Wadim Zudilin (personal communication) pointed out that (3.5) is a special case of the following identity [14, p. 80, (2.5.32)]:

$${}_2F_1 \left[\begin{matrix} a, b \\ c \end{matrix} ; z \right] {}_2F_1 \left[\begin{matrix} a, c-b \\ c \end{matrix} ; z \right] = (1-z)^{-a} {}_4F_3 \left[\begin{matrix} a, b, c-a, c-b \\ c, \frac{c}{2}, \frac{c+1}{2} \end{matrix} ; \frac{-z^2}{4(1-z)} \right],$$

by noticing the identity [14, p. 31, (1.7.1.3)]:

$$(1-z)^{-a} {}_2F_1 \left[\begin{matrix} a, b \\ c \end{matrix} ; -\frac{z}{1-z} \right] = {}_2F_1 \left[\begin{matrix} a, c-b \\ c \end{matrix} ; z \right].$$

Besides, the polynomial $d_n(x)$ is a particular case of classical Meixner orthogonal polynomials (see <http://homepage.tudelft.nl/11r49/askey/ch1/par9/par9.html>).

We also need the following new expression for $s_n(x)^2$, which is crucial in dealing with the last three polynomials in Theorem 1.1.

Lemma 3.2 *Let n be a non-negative integer. Then*

$$s_n(x)^2 = \sum_{k=0}^n \binom{n+k}{2k} \binom{x}{k} \binom{x+k}{k} \sum_{j=0}^k \binom{2k}{j+k} \binom{x}{j} \binom{x+j}{j}. \quad (3.6)$$

Proof. From the Pfaff-Saalschütz identity [1, (1.4)], we deduce that (see the proof of [9, Lemma 4.2])

$$\binom{x}{j} \binom{x+j}{j} \binom{x}{k} \binom{x+k}{k} = \sum_{r=k}^{j+k} \binom{j+k}{j} \binom{k}{r-j} \binom{r}{k} \binom{x}{r} \binom{x+r}{r}.$$

Therefore, comparing the coefficients of $\binom{x}{r} \binom{x+r}{r}$, we see that (3.6) is equivalent to

$$\begin{aligned} & \sum_{j=0}^n \sum_{k=0}^n \binom{n}{j} \binom{n}{k} \binom{j+k}{j} \binom{k}{r-j} \binom{r}{k} \\ &= \sum_{j=0}^n \sum_{k=0}^n \binom{n+k}{2k} \binom{2k}{j+k} \binom{j+k}{j} \binom{k}{r-j} \binom{r}{k}. \end{aligned} \quad (3.7)$$

Denote the left-hand side of (3.7) by A_n and the right-hand side of (3.7) by B_n . Then the multi-Zeilberger algorithm gives the following recurrences of order 3:

$$\begin{aligned} & (n+3)^2(2n-r+5)(2n-r+6)A_{n+3} - (12n^4 - 4n^3r + 3n^2r^2 + 110n^3 - 17n^2r \\ & + 14nr^2 + 394n^2 - 18nr + 17r^2 + 650n + r + 414)A_{n+2} + (12n^4 + 4n^3r + 3n^2r^2 \\ & + 82n^3 + 31n^2r + 10nr^2 + 226n^2 + 74nr + 9r^2 + 294n + 57r + 150)A_{n+1} \\ & - (n+1)^2(2n+r+2)(2n+r+3)A_n = 0, \end{aligned} \quad (3.8)$$

$$\begin{aligned} & (n+3)(2n+3)(2n-r+5)(2n-r+6)B_{n+3} - (2n+5)(4n^3 + 4n^2r + nr^2 + 30n^2 \\ & + 17nr + r^2 + 72n + 17r + 54)B_{n+2} - (2n+3)(4n^3 - 4n^2r + nr^2 + 18n^2 - 15nr \\ & + 3r^2 + 24n - 13r + 10)B_{n+1} + (n+1)(2n+5)(2n+r+2)(2n+r+3)B_n = 0. \end{aligned} \quad (3.9)$$

By induction on n , we may deduce from (3.8) and (3.9) that the numbers A_n and B_n also satisfy the same recurrence of order 2:

$$\begin{aligned} & (n+2)(2n-r+3)(2n-r+4)A_{n+2} - (2n+3)(4n^2 + r^2 + 12n + r + 10)A_{n+1} \\ & + (n+1)(2n+r+2)(2n+r+3)A_n = 0. \end{aligned}$$

Moreover, it is clear that $A_0 = B_0$ and $A_1 = B_1$ for any r . This proves that $A_n = B_n$ holds for all n . \square

Remark. If we apply the multi-Zeilberger algorithm to the right-hand side of (3.6) directly, then we will obtain a much more complicated recurrence of order 7. This is why we turn to consider the equivalent form (3.7) of the identity (3.6).

The following result can be easily proved by induction on n .

Lemma 3.3 *Let n and k be non-negative integers with $k \leq n$. Then*

$$\sum_{m=k}^{n-1} (2m+1) \binom{m+k}{2k} = \frac{n(n-k)}{k+1} \binom{n+k}{2k}. \quad (3.10)$$

Let

$$S_n(x_0, \dots, x_n) = \sum_{k=0}^n \binom{n+k}{2k} \binom{2k}{k} x_k.$$

be the multi-variable Schmidt polynomials. In order to prove Theorem 1.1, we also need the following result, which is a special case of [3, Theorem 1.1].

Lemma 3.4 *Let m and n positive integers and $\varepsilon = \pm 1$. Then all the coefficients in*

$$\sum_{k=0}^{n-1} \varepsilon^k (2k+1) S_k(x_0, \dots, x_k)^m$$

are multiples of n .

4 Proof of Theorem 1.1

Applying the identities (3.1) and (3.10), we have

$$\begin{aligned} \sum_{m=0}^{n-1} (2m+1) d_m(x)^2 &= \sum_{m=0}^{n-1} (2m+1) \sum_{k=0}^m \binom{m+k}{2k} \binom{x}{k} \binom{x+k}{k} 4^k \\ &= \sum_{k=0}^{n-1} \frac{n(n-k)}{k+1} \binom{n+k}{2k} \binom{x}{k} \binom{x+k}{k} 4^k. \end{aligned}$$

Therefore,

$$\frac{x(x+1)}{2n^2} \sum_{m=0}^{n-1} (2m+1) d_m(x)^2 = \sum_{k=0}^{n-1} \frac{(n-k)(k+1)}{2n} \binom{n+k}{2k} \binom{x+1}{k+1} \binom{x+k}{k+1} 4^k. \quad (4.1)$$

We now assume that x is a positive integer in (4.1). Then by Theorem 1.2 the k -th summand in the right-hand side of (4.1) is an integer for $k \geq 1$, and is equal to $\binom{x+1}{2}$ for $k = 0$. This proves the first polynomial in Theorem 1.1 is integer-valued.

Similarly, applying (3.6) and (3.10), we have

$$\frac{1}{n^2} \sum_{m=0}^{n-1} (2m+1) s_m(x)^2 = \sum_{k=0}^{n-1} \frac{1}{k+1} \binom{n-1}{k} \binom{n+k}{k} \binom{x+k}{2k} \sum_{j=0}^k \binom{2k}{j+k} \binom{x}{j} \binom{x+j}{j}, \quad (4.2)$$

which by Theorem 1.2 is clearly integer-valued.

For any non-negative integer k , let

$$\begin{aligned} x_k &:= \binom{x+k}{2k} 4^k, \\ y_k &:= \binom{x+k}{2k} \sum_{j=0}^k \binom{2k}{j+k} \binom{x}{j} \binom{x+j}{j}. \end{aligned}$$

Then the identities (3.1) and (3.6) may be respectively rewritten as

$$\begin{aligned} d_n(x)^2 &= \sum_{k=0}^n \binom{n+k}{2k} \binom{2k}{k} x_k, \\ s_n(x)^2 &= \sum_{k=0}^n \binom{n+k}{2k} \binom{2k}{k} y_k. \end{aligned}$$

It is clear that the numbers x_0, \dots, x_n and y_0, \dots, y_n are all integers when x is an integer. By Lemma 3.4, we see that the other four polynomials in Theorem 1.1 are also integer-valued.

5 Concluding remarks and open problems

A special case of a well-known ${}_3F_2$ transformation formula in [2, p. 142] gives:

$${}_3F_2 \left[\begin{matrix} -n, -x, x+1 \\ 1, 1 \end{matrix} ; 1 \right] = \frac{(x+1)_n}{n!} {}_3F_2 \left[\begin{matrix} -n, -x, -x \\ 1, -x-n \end{matrix} ; 1 \right],$$

i.e.,

$$s_n(x) = \sum_{k=0}^n \binom{n}{k} \binom{x}{k} \binom{x+n-k}{n}.$$

Let $p \geq 5$ be an odd prime. Z.-W. Sun [15, Conjecture 6.11] also conjectured that

$$\sum_{k=0}^{p-1} (2k+1) s_k(x)^2 \equiv \begin{cases} \frac{3}{4} \left(\frac{-1}{p} \right) p^2 \pmod{p^4}, & \text{if } x = -\frac{1}{2}, \\ \frac{7}{9} \left(\frac{-3}{p} \right) p^2 \pmod{p^4}, & \text{if } x = -\frac{1}{3}, \\ \frac{13}{16} \left(\frac{-2}{p} \right) p^2 \pmod{p^4}, & \text{if } x = -\frac{1}{4}, \\ \frac{31}{36} \left(\frac{-1}{p} \right) p^2 \pmod{p^4}, & \text{if } x = -\frac{1}{6}, \end{cases} \quad (5.1)$$

where $\left(\frac{\cdot}{p} \right)$ denotes the Legendre symbol modulo p .

It is easy to see that, for $0 \leq k \leq p-1$,

$$\binom{p-1}{k} \binom{p+k}{k} \equiv (-1)^k \pmod{p^2}.$$

Hence, letting $n = p$ in (4.2) and applying Theorem 1.2, we immediately obtain

Theorem 5.1 *Let p be a prime and x a p -adic integer. Then*

$$\sum_{k=0}^{p-1} (2k+1) s_k(x)^2 \equiv p^2 \sum_{k=0}^{p-1} \frac{(-1)^k}{k+1} \binom{x+k}{2k} \sum_{j=0}^k \binom{2k}{j+k} \binom{x}{j} \binom{x+j}{j} \pmod{p^4}. \quad (5.2)$$

We believe that the congruence (5.2) can be utilized to prove Sun's conjectural congruence (5.1). Unfortunately, we are unable to accomplish this work. We hope that the interested reader can continue working on this problem.

An identity similar to (3.1) is Clausen's identity [4]:

$${}_2F_1 \left[\begin{matrix} a, b \\ a+b+\frac{1}{2} \end{matrix} ; x \right]^2 = {}_3F_2 \left[\begin{matrix} 2a, 2b, a+b \\ 2a+2b, a+b+\frac{1}{2} \end{matrix} ; x \right], \quad |x| < 1. \quad (5.3)$$

It is well known that Clausen's identity (5.3) has three different q -analogues (see [6, (8.8.17) and (III.22)] and [10, 11]). It is natural to ask

Problem 5.2 Is there a q -analogue of the identity (3.1)?

Dziemiańczuk [5] considered weighted Delannoy numbers. The natural q -Delannoy numbers (see [5, p. 30]) are

$$D_q(m, n) := \sum_{k=0}^n q^{\binom{k}{2}} \begin{bmatrix} n \\ k \end{bmatrix} \begin{bmatrix} n+m-k \\ n \end{bmatrix}.$$

It is easy to see that

$$D_{q^{-1}}(m, n) = q^{-mn} \sum_{k=0}^n q^{\binom{k+1}{2}} \begin{bmatrix} n \\ k \end{bmatrix} \begin{bmatrix} n+m-k \\ n \end{bmatrix}.$$

It seems that a possible q -analogue of the left-hand side of (3.1) should be $q^{mn} D_q(m, n) D_{q^{-1}}(m, n)$ rather than $D_q(m, n)^2$. However, it is quite difficult to find the corresponding q -analogue of the right-hand side of (3.1).

The following conjecture is a q -analogue of (1.1) in the case where x is a positive integer.

Conjecture 5.3 *Let p be an odd prime and m a positive integer. Then*

$$\begin{aligned} & \sum_{k=0}^{p-1} \frac{1 - q^{2k+1}}{1 - q} D_q(m, k) D_{q^{-1}}(m, k) q^{-k} \\ & \equiv \begin{cases} \frac{1 - q^{-2m}}{1 - q^2} q \pmod{[p]^2}, & \text{if } m \equiv 0 \pmod{p}, \\ \frac{1 - q^{2m+2}}{1 - q^2} q \pmod{[p]^2}, & \text{if } m \equiv -1 \pmod{p}, \\ 0 \pmod{[p]^2}, & \text{otherwise,} \end{cases} \end{aligned}$$

where $[p] = 1 + q + \dots + q^{p-1}$.

Furthermore, a fascinating q -analogue of the first three expressions in Theorem 1.1 seems to be true.

Conjecture 5.4 *Let m , n , and r be positive integers. Then all of*

$$\begin{aligned} & \sum_{k=0}^{n-1} \frac{(1 - q^m)(1 - q^{m+1})(1 - q^{2k+1})}{(1 - q^2)(1 - q^n)^2} D_q(m, k) D_{q^{-1}}(m, k) q^{-k}, \\ & \sum_{k=0}^{n-1} \frac{1 - q^{2k+1}}{1 - q^n} D_q(m, k)^r D_{q^{-1}}(m, k)^r q^{-k}, \\ & \sum_{k=0}^{n-1} (-1)^{n-k-1} \frac{1 - q^{2k+1}}{1 - q^n} D_q(m, k)^r D_{q^{-1}}(m, k)^r q^{\binom{k}{2}} \end{aligned}$$

are Laurent polynomials in q with non-negative integer coefficients.

To prove Conjectures 5.3 and 5.4, perhaps we need to give a single-sum expression for $D_q(m, n)D_{q^{-1}}(m, n)$ and a q -analogue of Lemma 3.4. The latter is relatively easy, while the former is rather difficult because our proofs of (3.1) cannot be extended to the q -analogue case directly. By the way, we did not find any q -analogue of the other three polynomials in Theorem 1.1.

Finally, based on numerical calculations, we propose the following conjecture.

Conjecture 5.5 *Let m and n be positive integers. Then both*

$$\frac{1}{n} \sum_{k=0}^{n-1} (2k+1) d_k(x)^m s_k(x)^m \quad \text{and} \quad \frac{1}{n} \sum_{k=0}^{n-1} (-1)^k (2k+1) d_k(x)^m s_k(x)^m$$

are integer-valued.
